

DMD Fiber Optic Communication Principles

Overview

Differential mode delay (DMD) is a parameter used to characterize the propagation characteristics of optical fibers, particularly in multimode fiber optic systems. The group velocities of different modes in a multimode fiber are generally different, resulting in mode-dependent group delays for a given length of fiber. The DMD measurement is performed by scanning the optical source across the face of the fiber as shown below: Basically, the DMD is. If pulse spreading (due to DMD) is significant, the energy from one pulse spills into the time slot of the next pulse. After removal of the reference pulse temporal width, the DMD temporal width is determined at the 25% threshold level between the first leading edge and the last trailing edge of all traces encompassed between specified radial positions. The DMD Analyzer tool encapsulates the necessary equipment to.
