

# The cable tray makes a buzzing sound when power is supplied

## Overview

The most frequent culprit of a buzzing noise is the transformer within the power supply. Transformers work by changing voltage levels and can produce sounds when they are under load. My power supply is making a weird electrical buzzing sound, it's intermittent and isn't related to the load state of the pc, the same sound is also coming from the other end of the power cable that is attached to an extension. The buzzing sound you hear is often a manifestation of these components underlining certain electrical or mechanical issues. In professional settings, a power supply is designed to operate quietly, but various factors can lead to an audible humming or buzzing sound, which can often be quite. I woke up this morning to a faint constant buzzing sound from my PC (specs in signature), which upon close inspection came from the PSU, the Cooler Master MWE Bronze V2 650W (230v only version). The noise is consistent the whole time the PC is plugged in even if it's turned off and even when the O/I switch is off.
